# **Discussion 4: Algorithmic Complexity + Programming Paradigms**

### **Algorithmic Complexity: Definitions**

1. What is runtime? How do we measure it?

Runtime measures at what speed an algorithm/block runs. We measure this using the number of steps it takes. Note: We don't use time to measure runtime because computers have different speeds, so the time an algorithm takes to run differs from machine to machine.

2. If a function runs in O(n) time, that means it runs...

O in linear time at worst

O in linear time on average

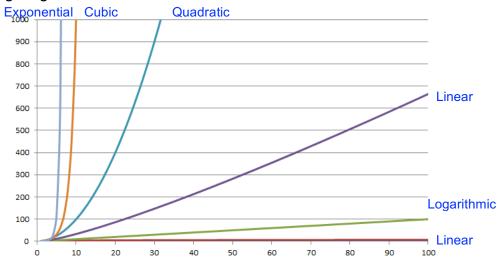

O in linear time at best

## **Understanding Runtimes**

1. Fill in the following chart:

Runtime	Notation	As input size increases by	The number of steps change by
Constant	O(1)	+1	No change
Logarithmic	O(log n)	x2	+1
Linear	O(n)	+1	+1
Quadratic	$O(n^2)$	x2	x4
Exponential (base B)	O(B <sup>n</sup> )	+1	xB

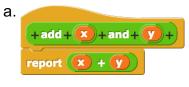

2. In the following diagram, label each of lines. Which is the best runtime? The worst?

b.

#### **Runtime: Practice**

1. Find the runtime of the following blocks or descriptions of blocks:

Constant

c.

Sort + list	+	Quadratic				
Sort +	Variables	Sorted list	min	min\_index		
Set	Sorted list	to	list			
repeat until	length of	list	=	0		
set	min\_index	to	1			
set	min\_index	to	list			
for		=	1	to	length of	list
if	item	i	of	list		
set	min\_index	to	i			
add	item	min\_index	of	list		
delete	min\_index	of	list			
report	sorted	list				
report	sorted	list				

d. This block takes in a value and a list and searches through every item in the list one by one to see if it can find that value.

Linear

e. This block takes in a value and a sorted list and searches for the value in the sorted list. Every iteration of the algorithm, it figures out which half of the list the value would be in, and then only searches in that half of the list.

Logarithmic (this is binary search, or find number in sorted list) from lab!

### **Programming Paradigms**

- 1. Write down the programming paradigm that **best** fits the following descriptions:
  - a. One sprite tells a second sprite to run some code. The second sprite does it. Object Oriented
  - b. You input a global list into a block. It reports a new list with different values, without modifying the input list. Functional
  - c. You give a program a condition as an input and it uses this condition to remove numbers from a list. You input a list and it removes items.
  - d. You have a global variable set to a secret word. You change the secret word every time you ask a player for a new secret word. Imperative
- 2. Match each of the following scripts to a programming paradigm:

**Functional Imperative Object Oriented** when 🔁 clicked Assume sum is a global create a clone of myself variable in the second script + Scaled + Sum + of + List : + Scaled + Sum + of + List : + script variables sum when I start as a clone set sum ▼ to 0 set sum v to 0 script variables (sum) 🕨 for i = 1 to length of List for i = 1 to length of List set sum v to 0 for j = 1 to length of List for j = 1 to length of List for i = 1 to length of List change sum by item j of List change sum ▼ by item j of List for j = 1 to length of List report sum change sum ▼ by item j of List report sum report sum

# Challenge

1. What does the following block do? What is its runtime?

This block reports true if there are only even numbers in the input list. Since HOFs take linear time, and the mod and equals blocks take constant time, this runs in linear time.

2. If myList is a list of n words, each of length n, what is the runtime of the following block?

Note: We will tell you when a block runs in linear time.

In this case, word -> list runs in linear time with respect to the length of the word. Since myList has n elements, map will do n actions, one for each element. For each element, word -> list takes n time, so the total runtime is  $O(n^2)$ .
